

ETL On AZURE

The use of Azure Data Factory, an ETL tool in Azure to assist us in performing Extract, Transform, and Load (ETL) processes for data

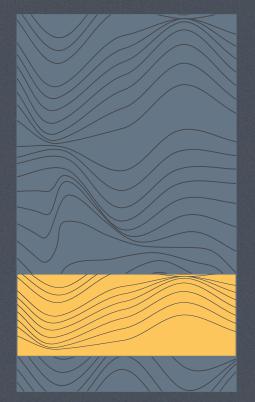

TABLE OF CONTENTS

Scenario 1

- a. Data from Source Mysql will be Transformed using Python and then loaded to Azure SQL Server
- b. Data from Source SQL Server will be Transformed using SSIS and then loaded to Azure SQL Server

Scenario 2

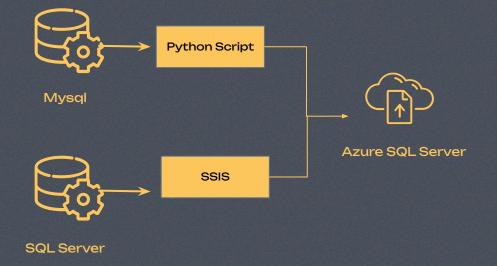

Data from SQL Server and Mysql will be extracted to Azure using Ms. The Integration Server Runtime then transformed and loaded using Azure Data Factory

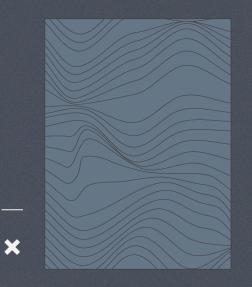

111

Python Script

On a python script

- Data from MySQL will be ingested into SQL Server Azure
- The Target Table is an empty table, with the addition of Source and Synch Date columns (Last time data was synch)
- Every time data is ingested into SQL Server Azure, the Last_synch column on MYSQL will be updated based on when the data was updated

Note: Weaknesses using Python Scripts takes long time to ingest data

Click to go to Script

Data Flow on Order Details Dataset.

- 1. OLE DB Source : Extraction Process
- Derived Column: Perform column transformation by adding the "Source" column (Data Source)
 And "Synch_date" for the time the data synch
- 3. Data Conversion: to perform data type conversions in data flow. The Data Conversion component allows you to change the column data type to a different data type according to your needs.
- 4. Lookup (Optional): to check the data if there is no duplicate data
- 5. OLE DB Destination: Load Data Location

Scenario 2

Workflow Explanation

₩|

- 1. Data from SQL Server Local will be extracted
- 2. Then use Linked Service to connect external data resources to the Azure Data Factory service
- 3. The Server on-premises setting in Azure refers to using Azure as a platform for hosting and managing servers that are physically located in local or on-premises environments.
- 4. Integration Runtimes are used to connect and manage access to data resources that reside in different locations and different technologies.
- 5. Pipelines in Azure are logical constructs used in Azure Data Factory to manage end-to-end workflows or data processes. Pipelines allow you to organize and direct data-related activities into structured series of actions.
- 6. On the Pipeline we can also set schedules in the form of triggers to debug or copy data

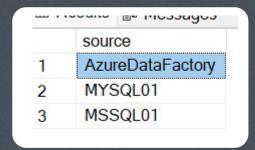

There are 3 data sources that have been successfully loaded into the Azure SQL Database

- MYSQL
- Microsoft SQL Server
- Azure Data Factory
